

Herdr Orchestrator

The orchestrator setup would work as follows.

There is a skill like `$herdr-work` that can be used to initiate work on a task.

The skill will use a script/daemon to do the following:

1. Setup the herdr workspace (worktree and branch)
2. Adds a `.herdr-work/issue-<number>-<name>.md` file for the agent to consume
3. Spins up the implementor and reviewer agent as two separate tabs and captures their herdr state to `.herdr-work/agents.json` for future reference and re-use
4. Create the `.herdr-work/tasks.json` file to manage the workflow state of the orchestration process
5. Then runs a daemon to monitor the workflow

The workflow will look roughly like the following

```
setup → ready_for_work → implementing → ready_for_review → reviewing → needs_fix →  
fixing → ready_for_review → review_approved → pr_review → awaiting_pr_review →  
merged/closed
```

The both `review` and `pr_review` can end up in either a `pass` or `fail` state.

for Review we work to `fix` in case of `fail` for the `implementor` to address issues and continue the loop.

1. Spins up the reviewer agent
